

starting position, so as to check whether the special detected signal is detected or not. In addition, the retrieving device regards the setting area adjacent to the setting area where the special detected signal detected last is recorded as the non-used setting area, when none of
5 the special detected signal is detected while the executing device is moved from the retrieval starting position to the predicted position.

According to this aspect, since the setting computer works so as to detect a non-used setting area based on the special detected signal while repeating the transition of the executing device from the retrieval
10 starting position to the predicted position and the update of the retrieval starting position, it is possible to detect the non-used setting area accurately.

In further aspect of the present invention, the recording parameter is intensity of an optical beam for use in the information
15 recording.

According to this aspect, use of a non-used setting area enables the accurate setting of the intensity of the recording optical beam.

In further aspect of the present invention, the setting program further causes the setting computer to function as a recording device
20 for executing the information recording by use of the set recording parameter.

According to this aspect, use of the accurately-set recording parameter enables the accurate and assured information recording.

The above object of the present invention can be achieved by a
25 computer data signal embodied in a carrier wave and representing a sequence of instructions of the present invention, which is executed by a setting computer, which is included in a recording parameter setting

apparatus for setting a recording parameter for use in optical information recording on the recording medium, using any one of a plurality of setting areas previously provided on the recording medium. The instructions is provided with the steps of: checking whether a
5 special detected signal is optically detected or not from the setting areas; retrieving a non-used area that is the setting area where no special detected signal is detected, of the setting areas, based on the check result of the step of checking; optically recording a mark signal for obtaining the special detected signal optically, in the detected non-
10 used setting area; recording a setting signal for setting the recording parameter, at least, in the non-used setting area excluding an area where the mark signal is recorded; and setting the recording parameter by optically detecting the recorded setting signal.

According to the present invention, since the setting computer
15 works so as to retrieve a non-used setting area by referring to the special detected signal to record the mark signal and the setting signal and so as to set the recording parameter by use of this recorded setting signal, it is possible to retrieve the non-used setting area accurately and set the recording parameter accurately by use of this. Therefore
20 use of the accurately-set recording parameter enables the accurate and assured information recording.

In one aspect of the present invention, the step of optically recording the mark signal records the mark signal at a position detected prior to the setting signal recorded in the non-used setting
25 area.

According to this aspect, since the setting computer works so as to record the mark signal at a position detected prior to the setting

signal, the accurate detection of the first detected position in the setting area enables accurate detection of a non-used setting area.

In another aspect of the present invention, the step of optically recording the mark signal repeats the recording of the mark signal at a
5 predetermined interval during the recording of the setting signal.

According to this aspect, since the setting computer works so as to record the mark signal at a predetermined interval during recording the setting signal, it is possible to prevent from a detection mistake of a non-used setting area caused by detecting no special setting signal for
10 a long time.

In further aspect of the present invention, the step of checking is further provided with the steps of: retrieving a predicted position of the setting area on the recording medium where the special detected signal is to be optically detected; moving an executing device for detecting the
15 setting signal and the special detected signal, from the retrieved predicted position, to a retrieval starting position on the recording medium distant from there at least by a distance corresponding to the predetermined interval; and repeating an operation of further moving the executing device again from the special detected signal-detected
20 position on the recording medium to a position on the recording medium distant from there at least by a distance corresponding to the predetermined interval, when the special detected signal is detected while the executing device is moved from the retrieval starting position to the predicted position, and further moving the executing device to
25 the predicted position, from a position of the executing device after the above further moving used as the retrieval starting position, so as to check whether the special detected signal is detected or not, and the
